

Towards advances in modelling of heavy precipitation by the synergetic use of convection-permitting simulations and state-of-the-art observations

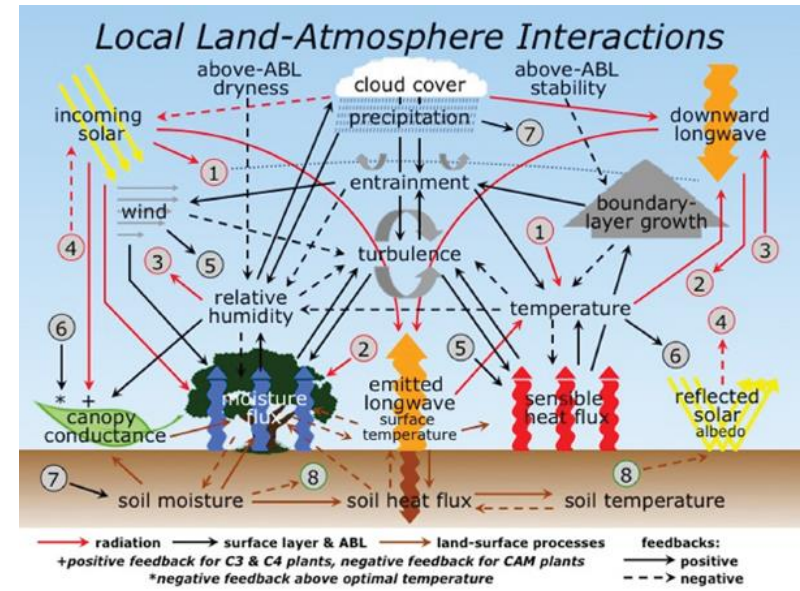

S. Khodayar, A. Caldas and S. Helgert

Institut of Meteorology and Climate Research, Karlsruhe Institute of Technology (KIT)

Challenge

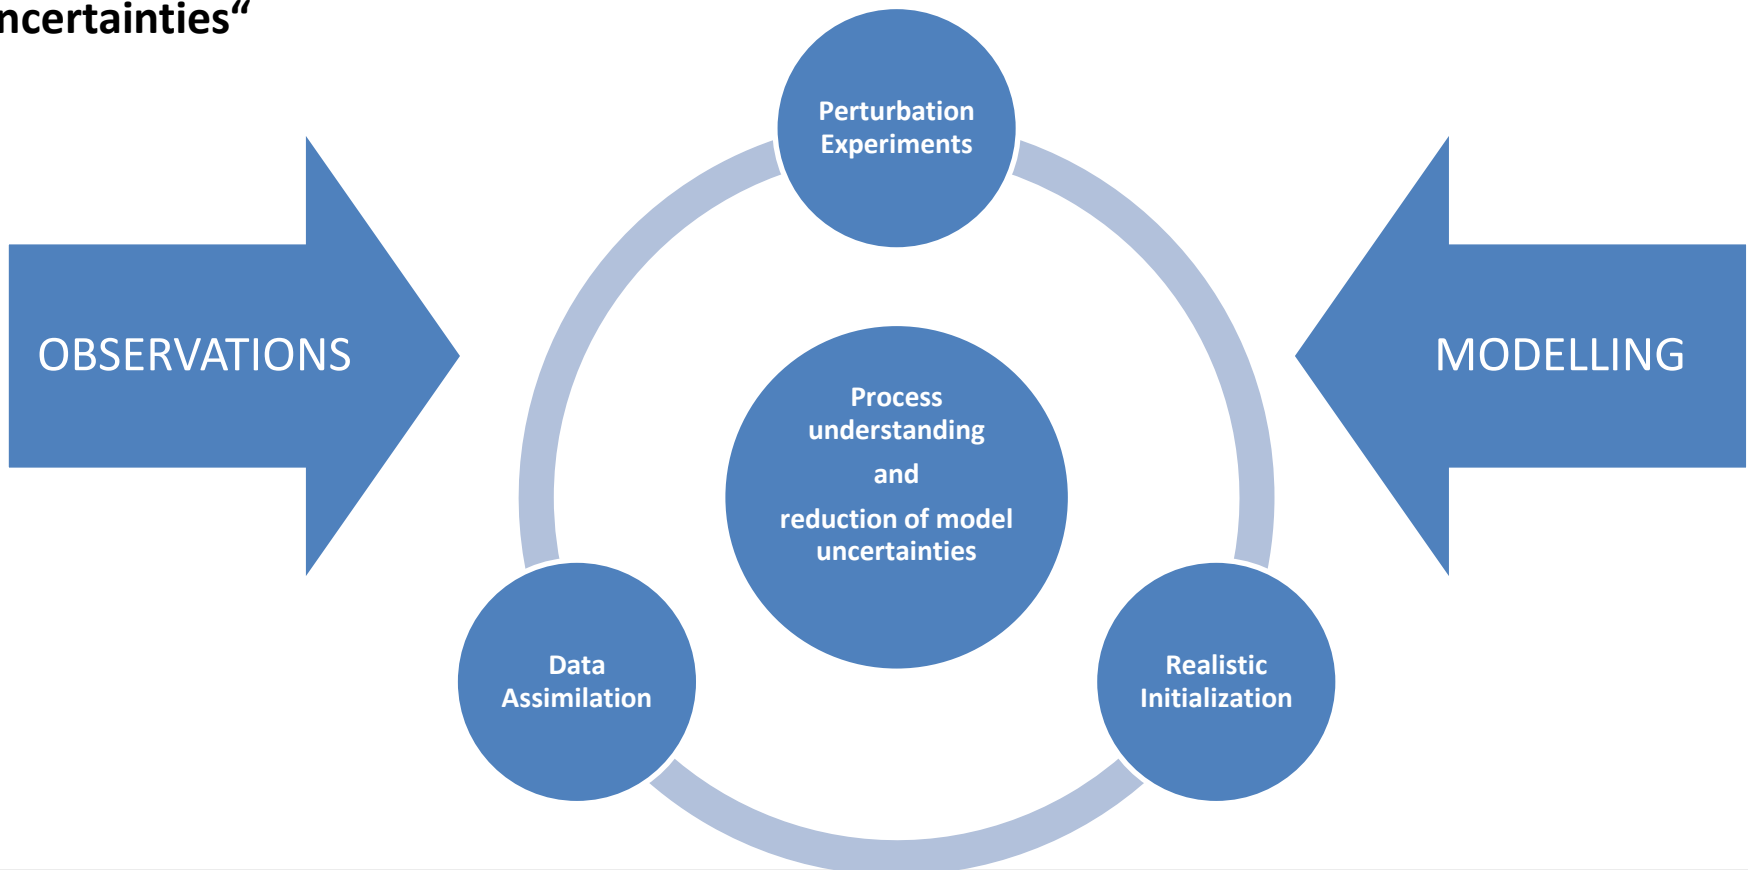

- In addition to large-scale drivers, **understanding specific processes and feedbacks acting at local to regional scales** is essential to understand the genesis and evolution of extreme events.
- A **misrepresentation of feedback mechanisms** in models is an important source of **uncertainty**.
- Processes and **feedbacks** contributing to the occurrence of extreme phenomena **are complex and manifold**. We focus our efforts in two components of the WC and related feedbacks: **the soil water content and the atmospheric moisture**.

Goals and Research Methodology Strategy

„Process-based evaluations across space/time scales using the synergy of state of the art technologies and high-resolution modelling to improve understanding and reduce model uncertainties“

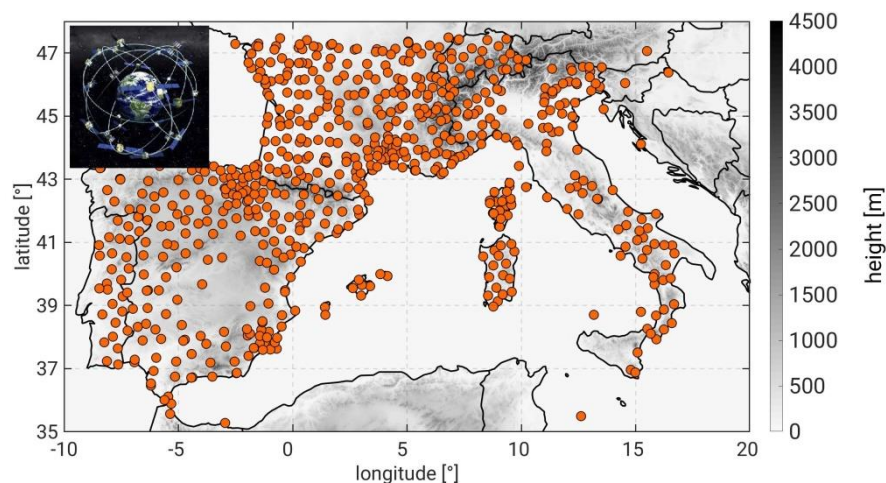

MODELLING

OBSERVATIONS

Experimental field campaign

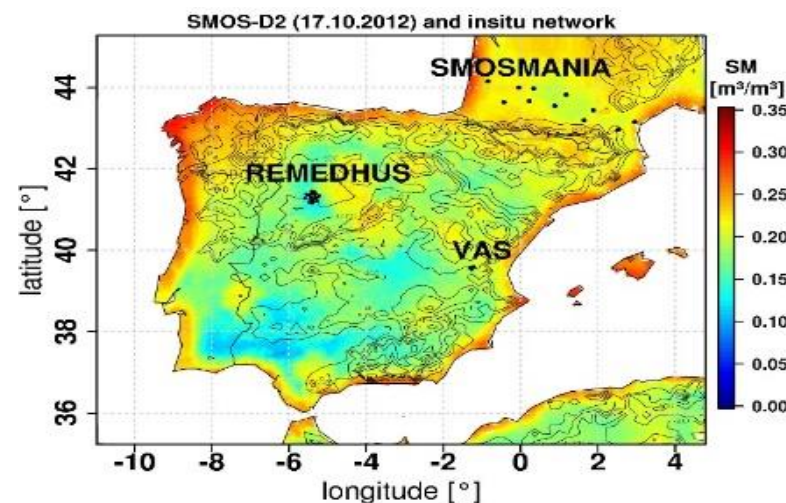

HyMeX (Hydrological Cycle in the
Mediterranean Experiment)

Position of GPS stations from several European networks, jointly post-processed to offer a unique merged product with a 10-minute frequency in the framework of HyMeX

Remote sensing products

SMOS (Soil Moisture Ocean Salinity)
space mission

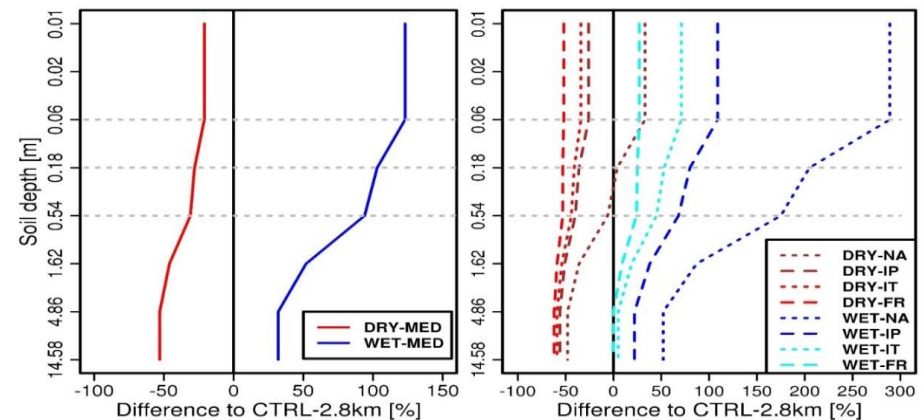

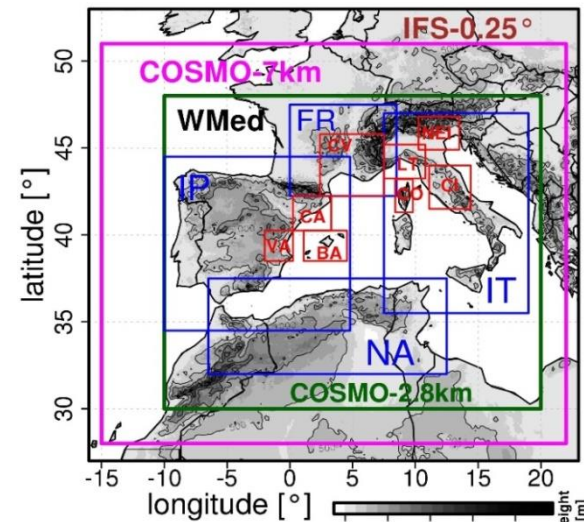

SMOS disaggregated 1 km product over the Iberian Peninsula

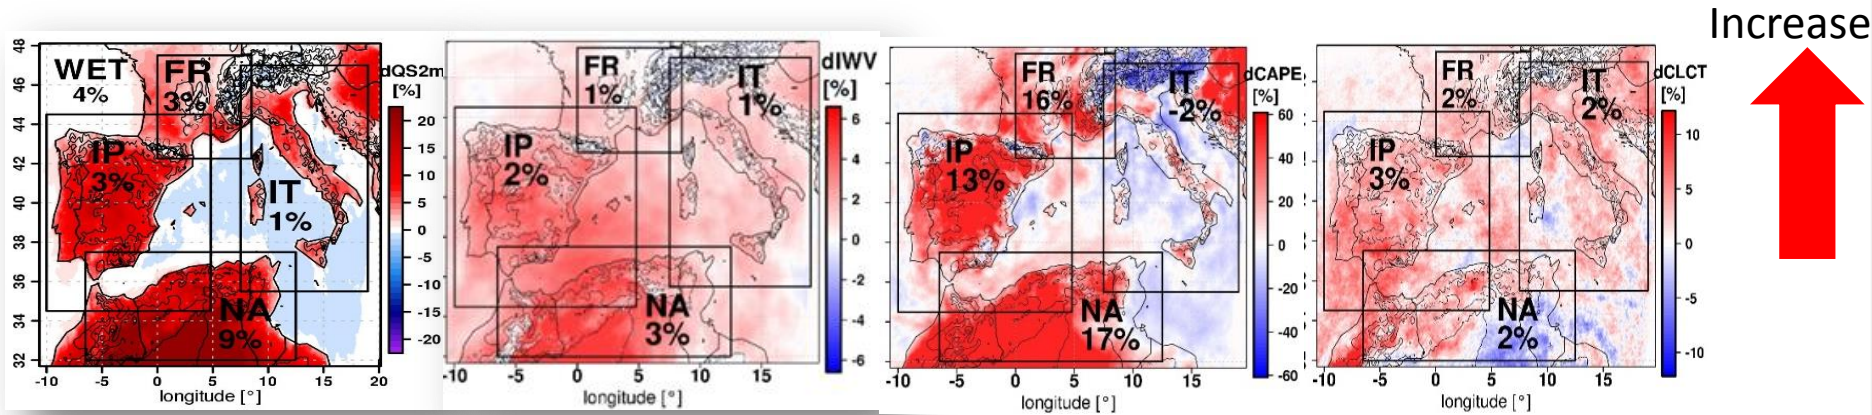

Relevance of extreme soil conditions for seasonal precipitation in the WMed

- COSMO-CLM seasonal SON 2012
- ECMWF-IFS -> 7 km -> 2.8 km
- ½ month spin up time
- 2 sensitivity experiments + CTRL
 - **WET** initial SM scenario
Every GP set to max field capacity
 - **DRY** initial SM scenario
Every GP set to min wilting point

- Impact regional dependent
- Higher impact: WET on dry areas

Impact on atmospheric conditions → Positive feedback, different strenghts

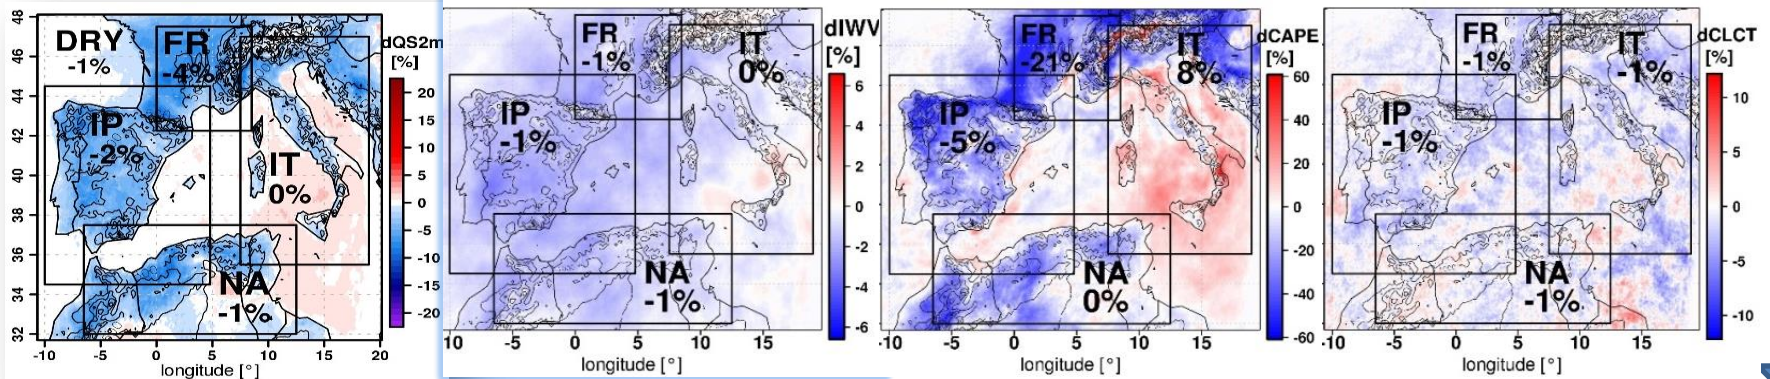

Humidity 2m

Modelling of atmospheric water vapour

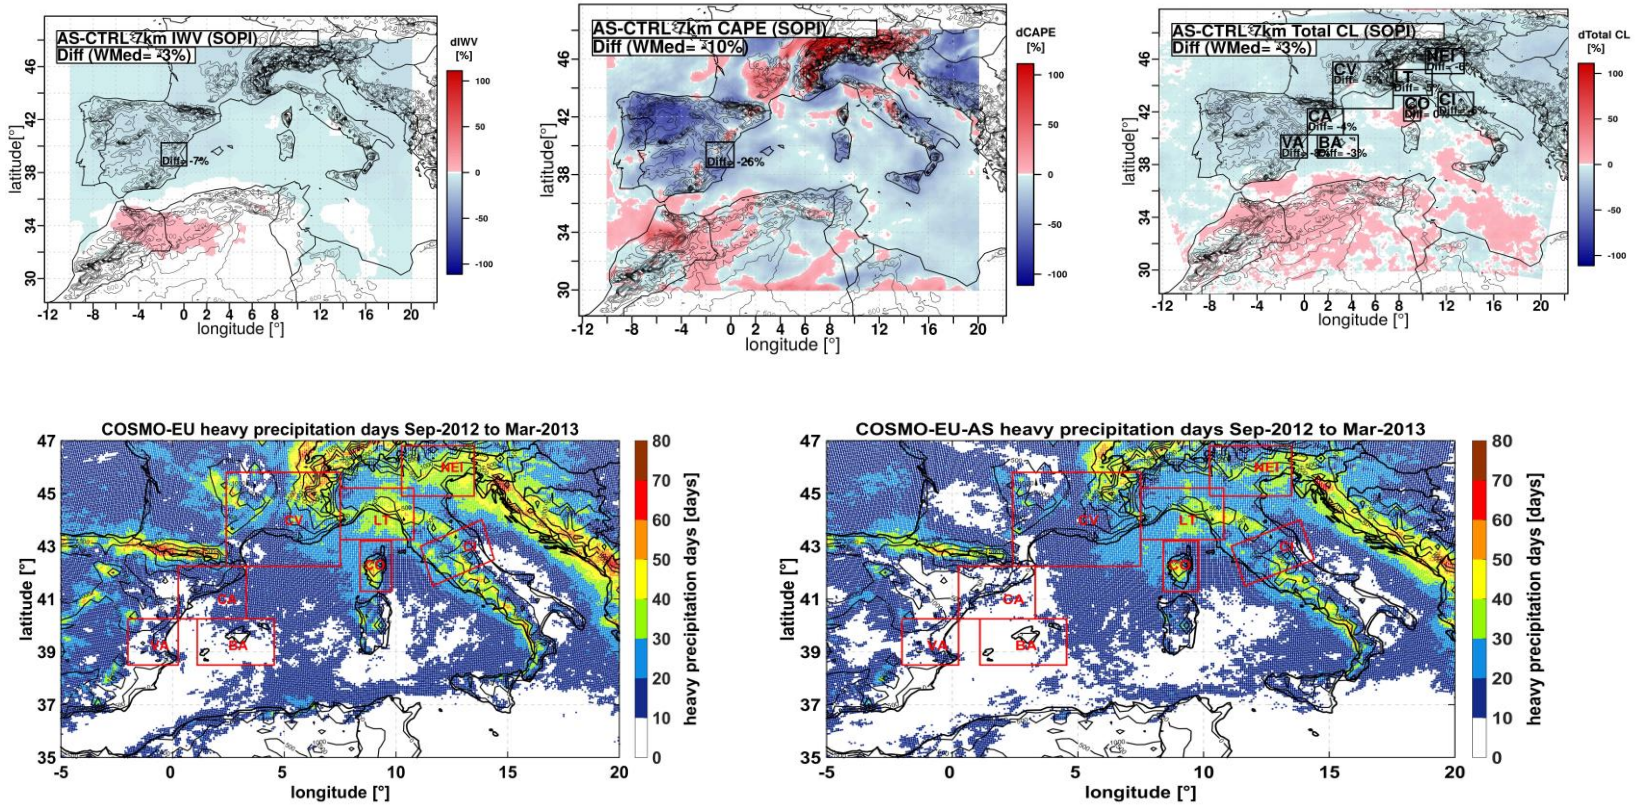

How accurate is atmospheric moisture modelling?

Impact of GPS-IWV assimilation

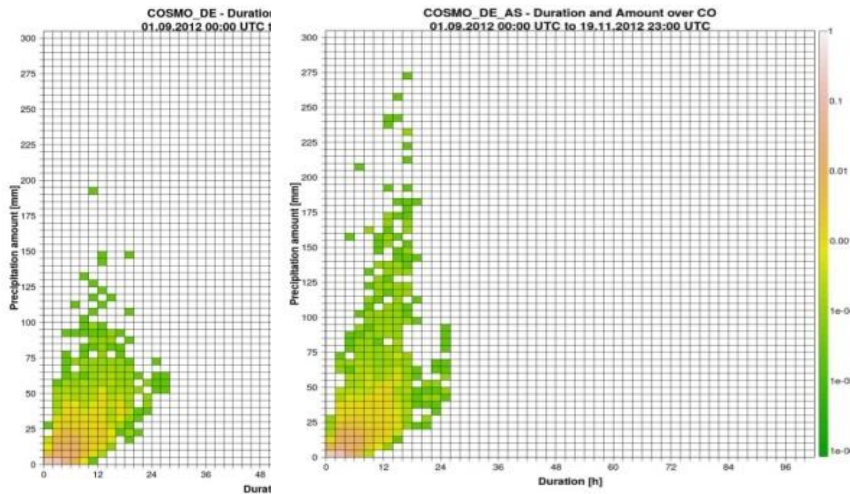

Impact of GPS-IWV assimilation on atmospheric conditions and precipitation

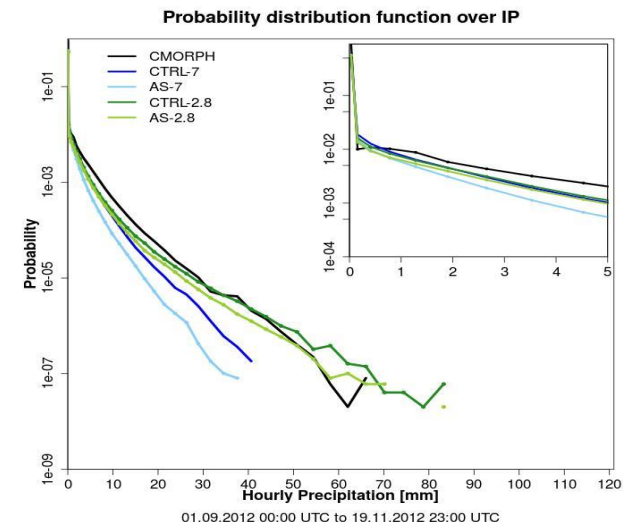

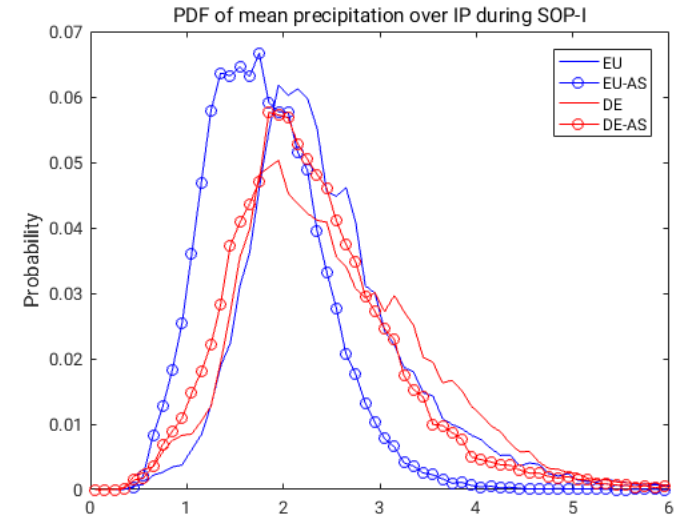

The number of wet days (with precipitation over 10 mm/day) is reduced

Impact on precipitation

- EU-7 km CTRL vs AS → change in the mean and in the variability
- DE-2.8 km CTRL vs AS → Increase in the mean, reduction in the higher extreme

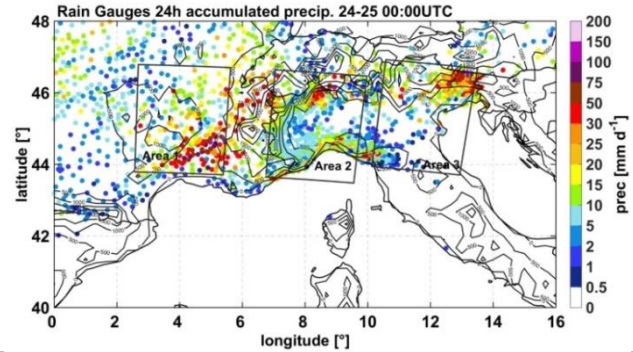

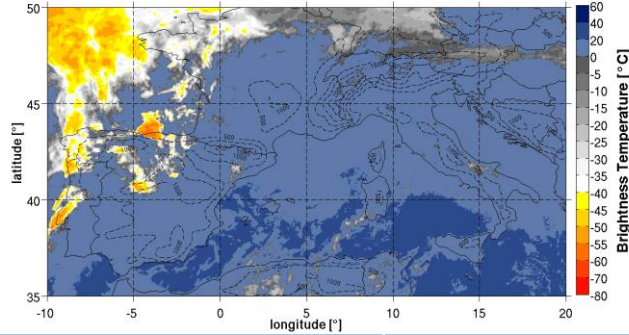

- Increase in short-duration large-amount precipitation events

Impact on HP modelling on IOP6: GPS-IWV assimilation across resolution

MSG IR10.8 Brightness Temperature

Assimilated

Negative impact on HP modelling on IOP6: GPS-IWV assimilation across resolution

DA drying the atmosphere 6 hours prior to CI
every horizontal grid resolution
Large vertical stratification discrepancy

GPS+RAD ASSIMILATION

RAD affects structure and location,
GPS modulates amount

Conclusions

- In this study, we address:
 - (a) The benefit of using a combination of CRM and state-of-the-art observations to improve modelling of heavy precipitation.
 - (b) The contribution of soil conditions, atmospheric moisture characteristics and related feedbacks on the occurrence of heavy precipitation events.
- We identified a **positive soil moisture-atmosphere-precipitation feedback in the WMed subregions across model resolution.**
- Definition of **initial soil moisture conditions** with high-resolution **disaggregated 1 km soil moisture** from state of the art satellite missions shows promising results.
- A perturbation in the initial soil moisture scenarios directly affects **boundary layer thermodynamic** (increase of θ_{e}) **and dynamical processes** (modification of convergence fields). Thus, mechanisms that lead to the occurrence of extreme precipitation events.

Conclusions

- The **assimilation** of total column water vapour information (**GPS-IWV**) significantly **improves the modelling** accuracy of this variable over the whole Wmed.
- We identify a **clear impact on the modelled precipitation**, especially of the intense events, for the three grid spacings (7km, 2.8km and 500m). In general, **higher resolution GPS-IWV assimilated runs show better agreement** with precipitation observations over the autumn period. But, this is not always the case for individual events.
- The **assimilation of GPS-IWV modulates the precipitation amount**, but neither the structure or location of precipitation are largely corrected/affected.
- A better definition of the vertical stratification of atmospheric moisture is crucial to improve the modelling of HP. The **combination of GPS-IWV and RAD assimilation at high resolution reveals the better results**.
- The assimilation of selected radiosondes (upstream of hot spots for each region/TGA) in combination with GPS-IWV information could be promising.
